

CSS Breakpoints for Responsive Design

© L. Hernández, 2024

Introduction

Users access the web with devices that have different screen sizes.

We need to implement a way to display websites properly on those screens to ensure usability.

Introduction

Responsive web design is a CSS-based design technique that ensures webpages render properly across all screen sizes and resolutions while ensuring usability.

Evolution of responsive design

HTML is fundamentally responsive.

If we create a webpage using only HTML and resize the window, the browser will automatically adjust the text to fit the viewport.

But the content won't look good on every screen.

Evolution of responsive design

For example, long lines of text can be difficult to read on a wide monitor.

Similarly, if the line length is reduced with CSS by creating columns or adding a margin, the content may look squashed when viewed on a mobile device.

Evolution of responsive design

We have to intervene to adapt the style to the screen based on the content and layout of the webpage.

Mobile Tablet

Antonio Gaudi

The voices of Barcelona blur in a mix of Spanish and Catalan in much the way Gaudi's work blurs the lines between architecture and artwork.

From the tiled benches in Guell Park to the towers over Casa Mila and Casa Batlló, I fell in love with Gaudi's work on my first trip to Barcelona.

Park Guell

The benches as Lizard fountain in Park Guell make up part of the UNESCO World Heritage Site known as, "The Works of Antonio Gaudi."

The park features Gaudi's famous Lizard Fountain, as well as benches and other extraordinary examples of Gaudi's talent with tiles.

Casa Batlló

The first time I strolled down the Passeig de Gràcia (Catalan for the Promenade of Grace), I stopped in my tracks in front of Gaudi's Casa Batlló.

The 'house', wedged between two 'normal' buildings, looks more like a giant sculpture than any houses I'd ever seen anywhere else.

Casa Mila

A popular attraction in Barcelona, Casa Mila, also known as La Pedrera, is arguably one of the most famous buildings designed by Gaudi.

The roof features a collection of chimneys and towers that like they'd fit right in as characters in a Dr. Seuss book.

Responsive web design

We can use **float** for layouts and media queries to query browser width or height to create layouts for different breakpoints using **CSS**.

We could also use fluid grids, fluid images, and media queries to create responsive content.

ADAPTIVE

Generates templates which are optimized and unique for every device class

RESPONSIVE

Universal design which reflows across displays

1

Media Queries

A way to apply CSS rules to the page based on the size of the displaying browser.

2

Fluid Grids

A percentage based design that adapts to the screen size accordingly.

Responsive web design

A breakpoint is a point, usually a specific width, at which a webpage's style is changed to ensure best possible user experience.

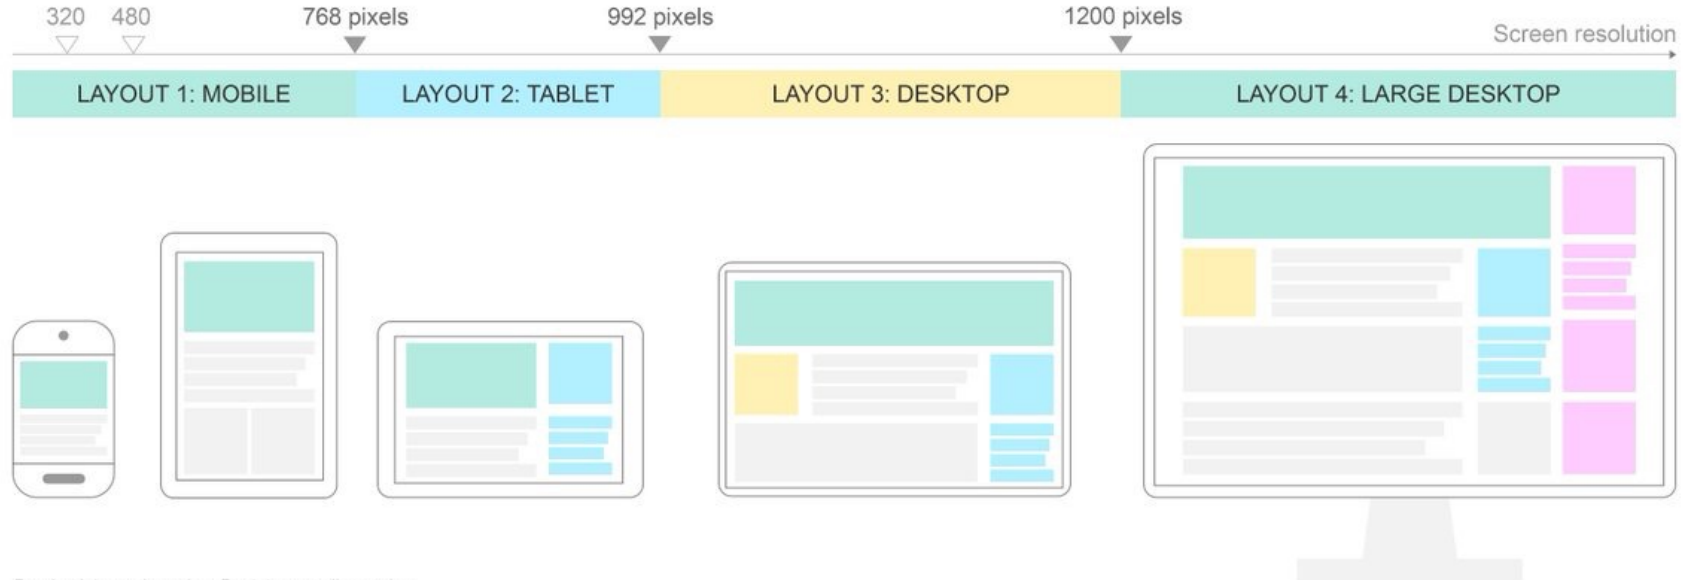

There is no strict rule or standard to define responsive breakpoints because there are so many different screen sizes.

Responsive web design

Creating more device breakpoints offers best results but it increases web design time and delays product delivery.

Creating fewer breakpoints boosts responsive design time but generates fewer layout variations affecting usability.

Responsive web design

0-480px

Smart Phones

481-768px

Tablets

769-1279px

Laptops

>= 1280px

Desktops

Breakpoint 0

Breakpoint 2

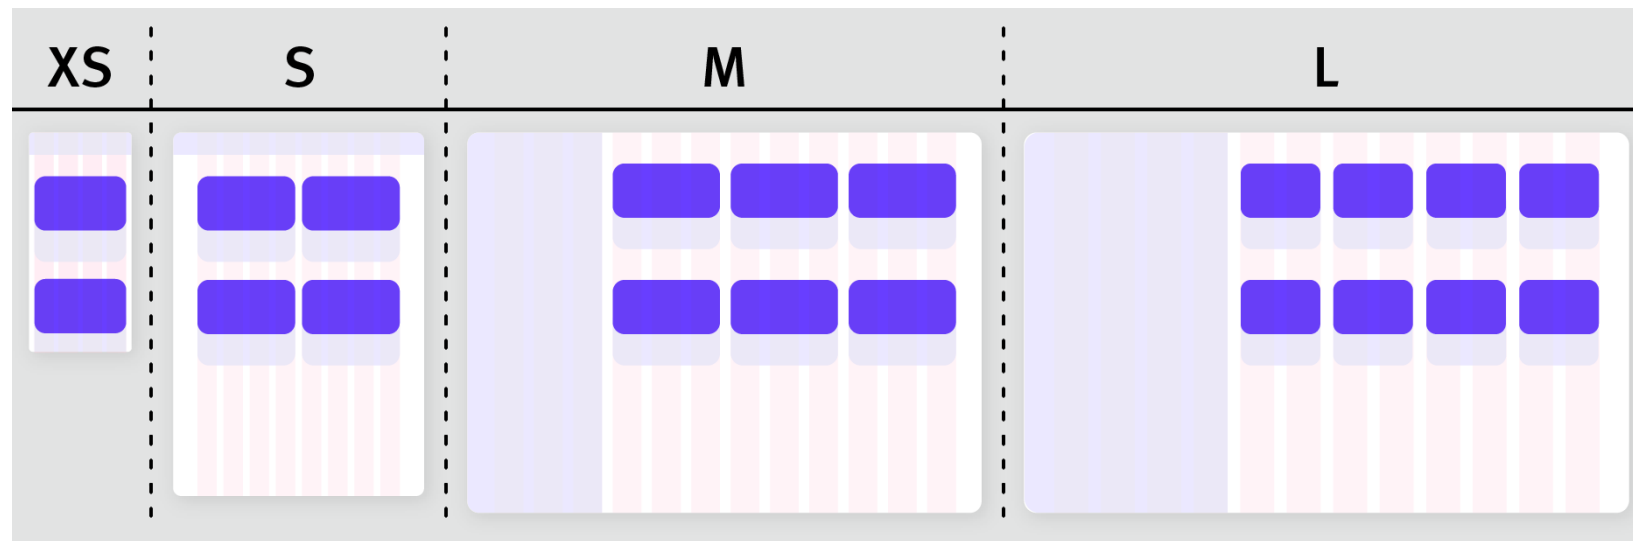

Breakpoint 3

Responsive web design

CSS frameworks like Bootstrap rose in popularity because they provided us with responsive grid systems that use pre-defined breakpoints to implement responsive layouts.

Responsive web design

Inbuilt CSS layout implementation methods have responsive capabilities such as Flexbox and CSS Grid.

Other modern methods have been developed to make content responsive without even using responsive layout libraries.

Responsive web design

- **clamp() function**: Allows typography and spacing to be responsive to viewport width.
- **Logical properties**: Permits spacing to be responsive to website.
- **Container queries**: Enables an HTML element to be responsive based on its dimensions.

Media Query

● Viewport width

Container Query

● Container width

Media queries

Media queries are useful when we want to modify layout or appearance of a site depending on specific system or browser characteristics.

Browser characteristics such as screen resolution of device or browser viewport width/height.

Media queries

Desktop

@media screen and
(min-width: 1024px)
{...}

Tablet

@media screen and
(min-width: 768px) and
(max-width: 1023px)
{...}

Smartphone

@media screen and
(max-width: 767px)
{...}

Media queries

The media type (all, print, or screen) is optional; it is assumed to be all if omitted.

This is the common syntax for a CSS media query.

The logical operators not, and, only, and or can be used to compose a complex media query.

```
@media <type> <operator> (feature) ... {  
  /* CSS rules */  
}
```

Media queries

For responsive design, **min-width** and **max-width** are the most commonly used media features.

These media features can help us create responsive breakpoints based on specific width ranges of the viewport.

Media queries

For example, this CSS code will apply styles only if browser's viewport width is equal to or less than 80em.

```
@media (max-width: 80em) {  
  /* CSS rules */  
}
```

New media queries specification includes some syntax improvements.

```
@media (width <= 80em) { ... }
```

Choose breakpoints

There are two main approaches when choosing CSS breakpoints: one is based on devices and other is based on content.

Breakpoints based on devices

With the variety of devices available, determining breakpoints based on screen sizes is challenging.

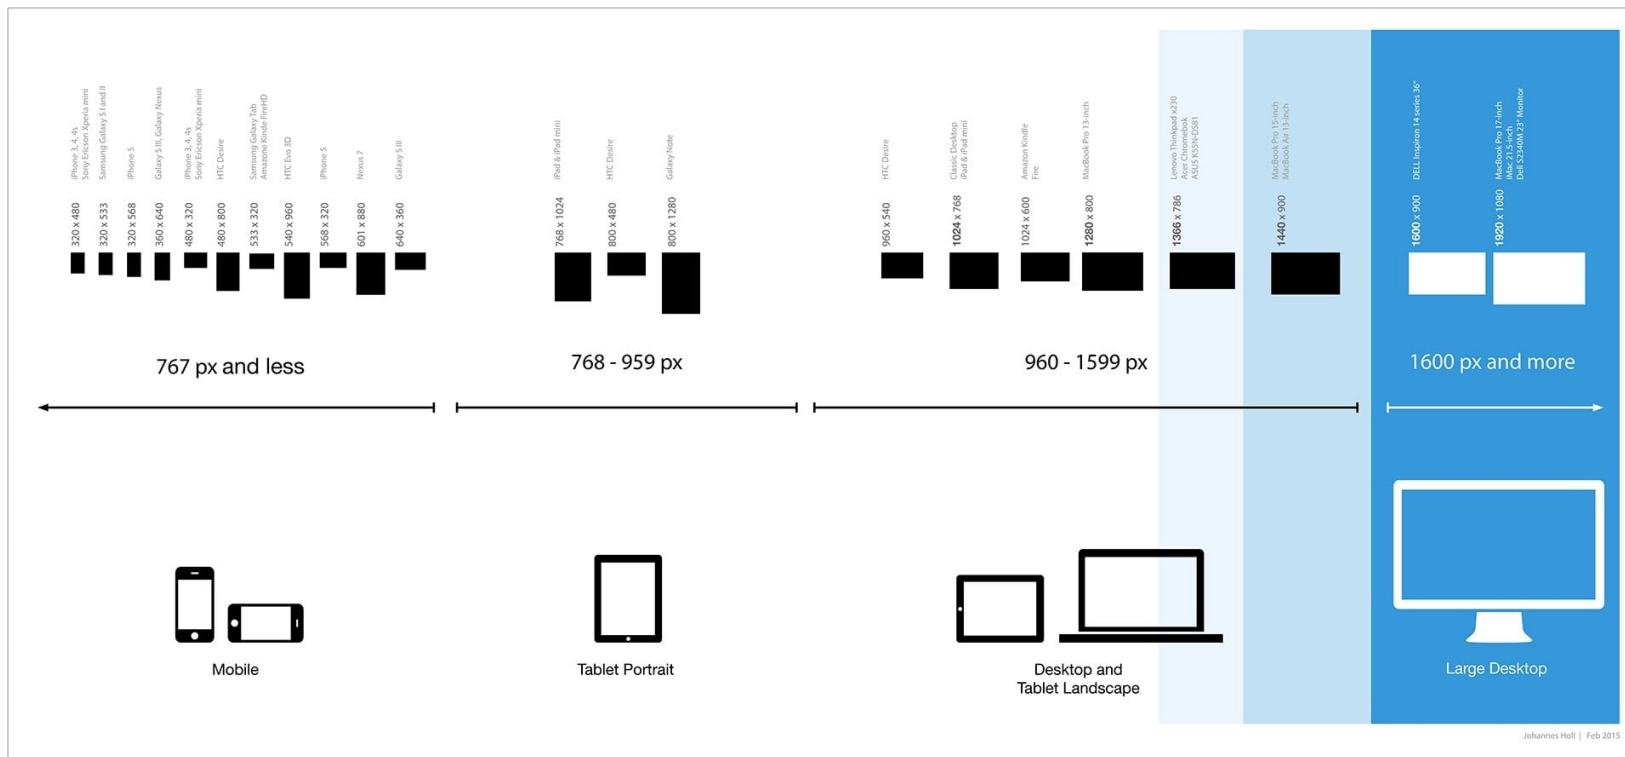

This approach is really not feasible to maintain.

Breakpoints based on devices

To simplify this approach, we could group devices based on a range of sizes.

The most common way is to group devices based on form factor (e.g., mobile devices, tablets, laptops, etc.).

Breakpoints based on devices

Breakpoints based on devices

Let's check several common breakpoints that most websites nowadays use.

This CSS example uses some breakpoints with a mobile-first design strategy (default style is for the smallest screen group).

**/* Default: Extra-small devices such as small phones
(less than 640px) */**

**/* Small devices such as large phones (640px and up) */
@media only screen and (min-width: 640px) {...}**

**/* Medium devices such as tablets (768px and up) */
@media only screen and (min-width: 768px) {...}**

**/* Large devices such as laptops (1024px and up) */
@media only screen and (min-width: 1024px) {...}**

**/* Largest devices such as desktops (1280px and up) */
@media only screen and (min-width: 1280px) {...}**

RESPONSIVE DESIGN

MOBILE FIRST DESIGN

A CSS example that only defines two breakpoints with a desktop-first design strategy (default style is for the largest screen group).

/ Default: Large devices such as laptops, computers
(greater than 1024px) **

/ Medium devices such as tablets (1024px or lesser) */
@media only screen and (max-width: 1024px) {...}*

/ Small devices such as phones (768px or lesser) */
@media only screen and (max-width: 768px) {...}*

Breakpoints based on devices

This example renders a responsive login section for desktop, tablet, and mobile screens.

```
<!DOCTYPE html>
<html lang="en">
  <head>
    <meta charset="UTF-8" />
    <meta name="viewport"
      content="width=device-width, initial-scale=1.0" />
    <meta http-equiv="X-UA-Compatible" content="ie=edge" />
    <title>Responsive design breakpoints example</title>
    <style>
      ...
    </style>
  </head>
  ...
```

```
* {  
  margin: 0;  
  padding: 0;  
  box-sizing: border-box;  
}  
  
.form-box {  
  display: flex;  
  justify-content: flex-end;  
  gap: 8px;  
  padding: 8px;  
  background-color: #333;  
  text-align: center;  
}  
...
```

...

```
.form-box input,  
.form-box button {  
    padding: 8px;  
    margin-right: 4px;  
    font-size: 14px;  
}
```

```
.form-box input {  
    outline: none;  
    border: none;  
}
```

...

...

```
.form-box button {  
  border: none;  
  background-color: #edae39;  
}
```

```
@media only screen and (max-width: 1024px) {
```

```
  .form-box input,  
  .form-box button {  
    display: block;  
    width: 100%;  
    font-size: 16px;  
  }  
}
```

...

...

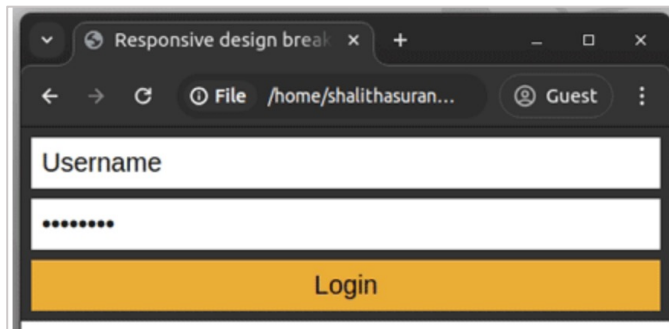

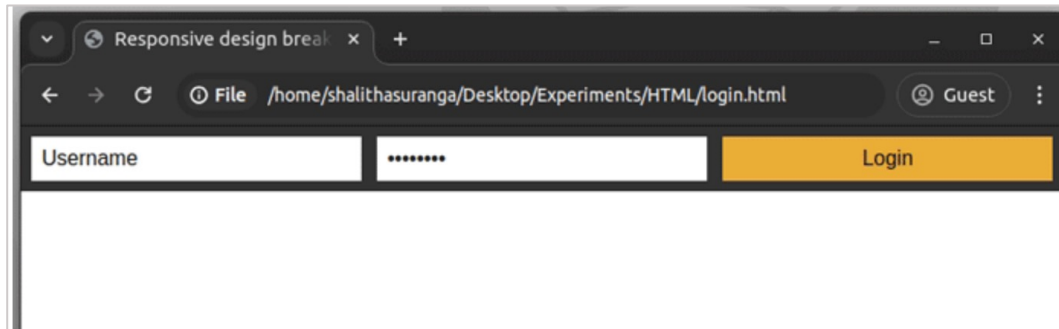

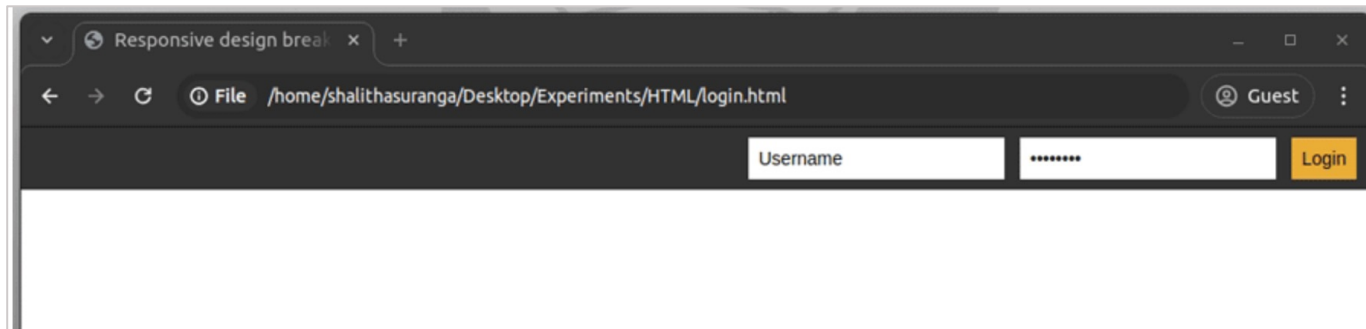

```
@media only screen and (max-width: 768px) {
```

```
.form-box {  
  flex-direction: column;  
}
```

```
.form-box input,  
.form-box button {  
  display: block;  
  width: 100%;  
  font-size: 20px;  
}
```

```
}
```

```
<!DOCTYPE html>
<html lang="en">
  <head>
    ...
  </head>
  <body>
    <div class="form-box">
      <input type="text" value="Username" />
      <input type="password" value="Password" />
      <button>Login</button>
    </div>
  </body>
</html>
```

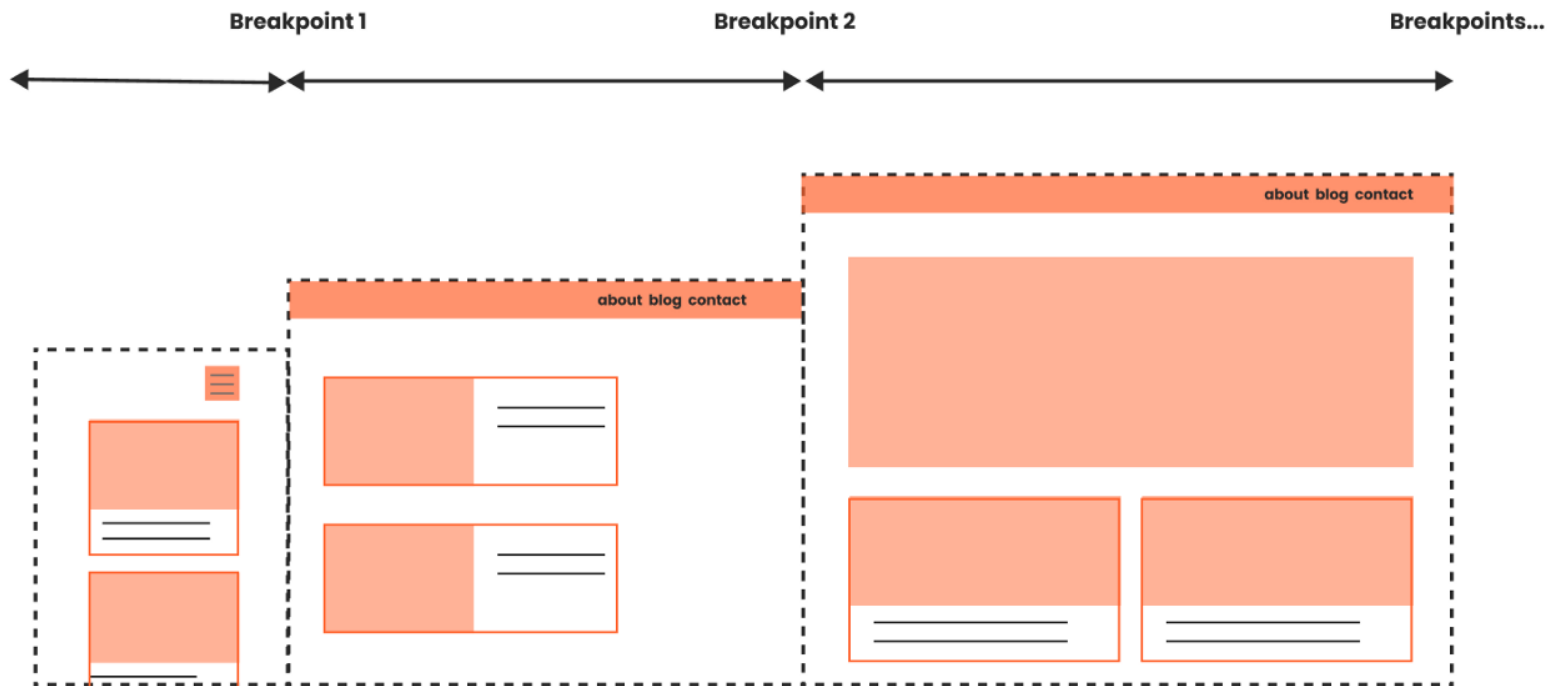

Breakpoints based on content

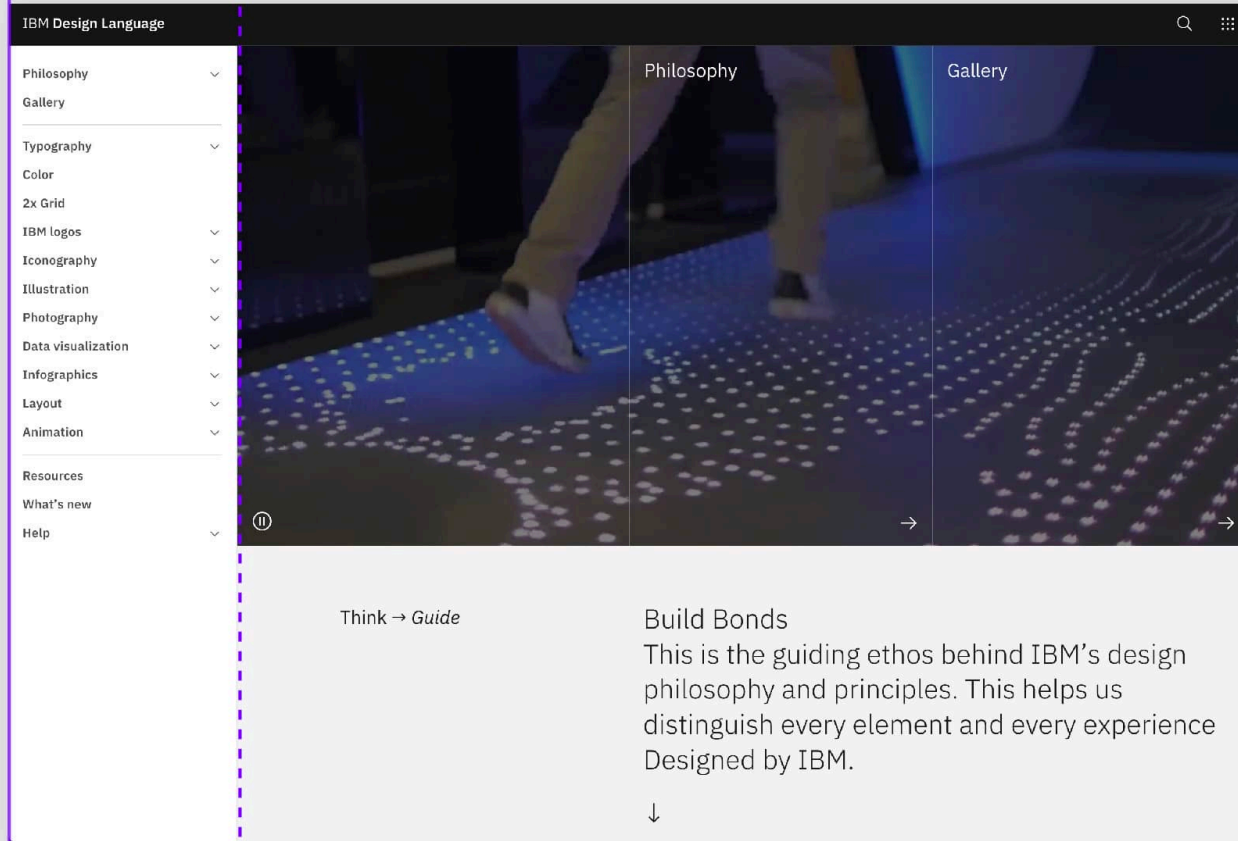

This approach is based on changing the design at the point where the content starts to break in some way.

If line lengths become too long, or if a section becomes too squashed, that's where we need to consider changing the style.

Breakpoints based on content

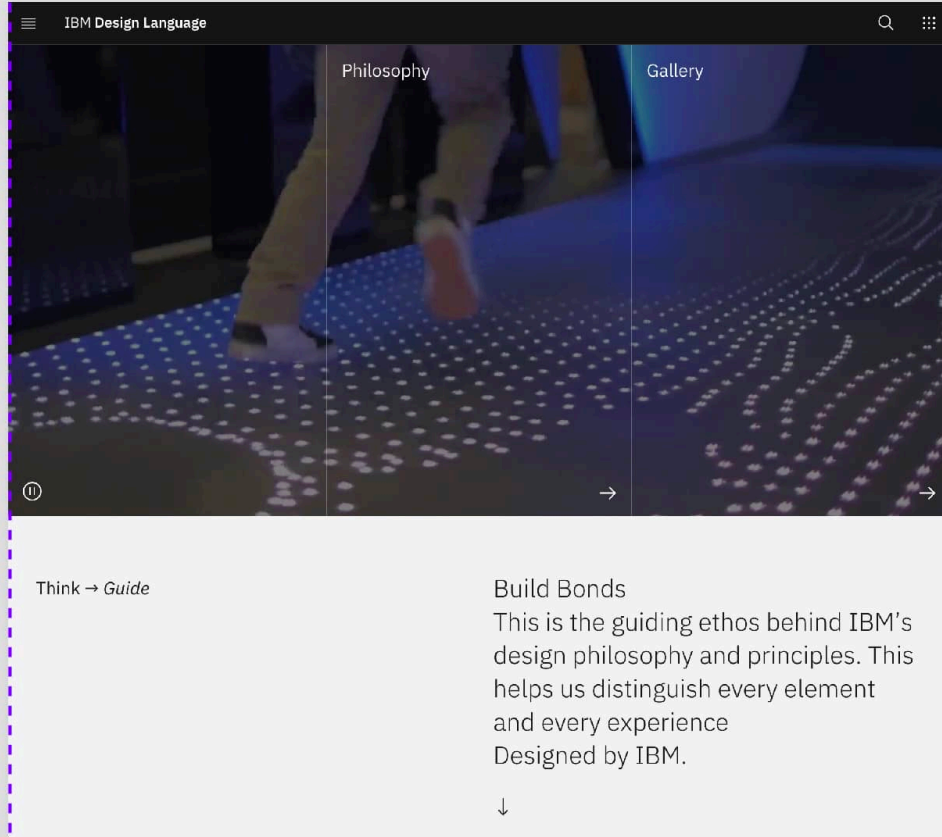

Large Screen Size

Medium
Screen Size

*COLLAPSED →

NN/g

Breakpoints based on content

Responsive mode in browser developer tools (Firefox and Chrome DevTools) is very useful for working out where our breakpoints should go.

We can easily make the viewport smaller or larger to see where the content style could be improved.

Breakpoints based on content

Here, the login form is not correctly getting rendered when the width is less than 486px, so we can create a breakpoint using max-width.

```
@media only screen and (max-width: 485px) {
```

```
  .form-box {  
    flex-direction: column;  
  }
```

```
  .form-box input,  
  .form-box button {  
    display: block;  
    width: 100%;  
  }  
}
```
